01 · System architecture

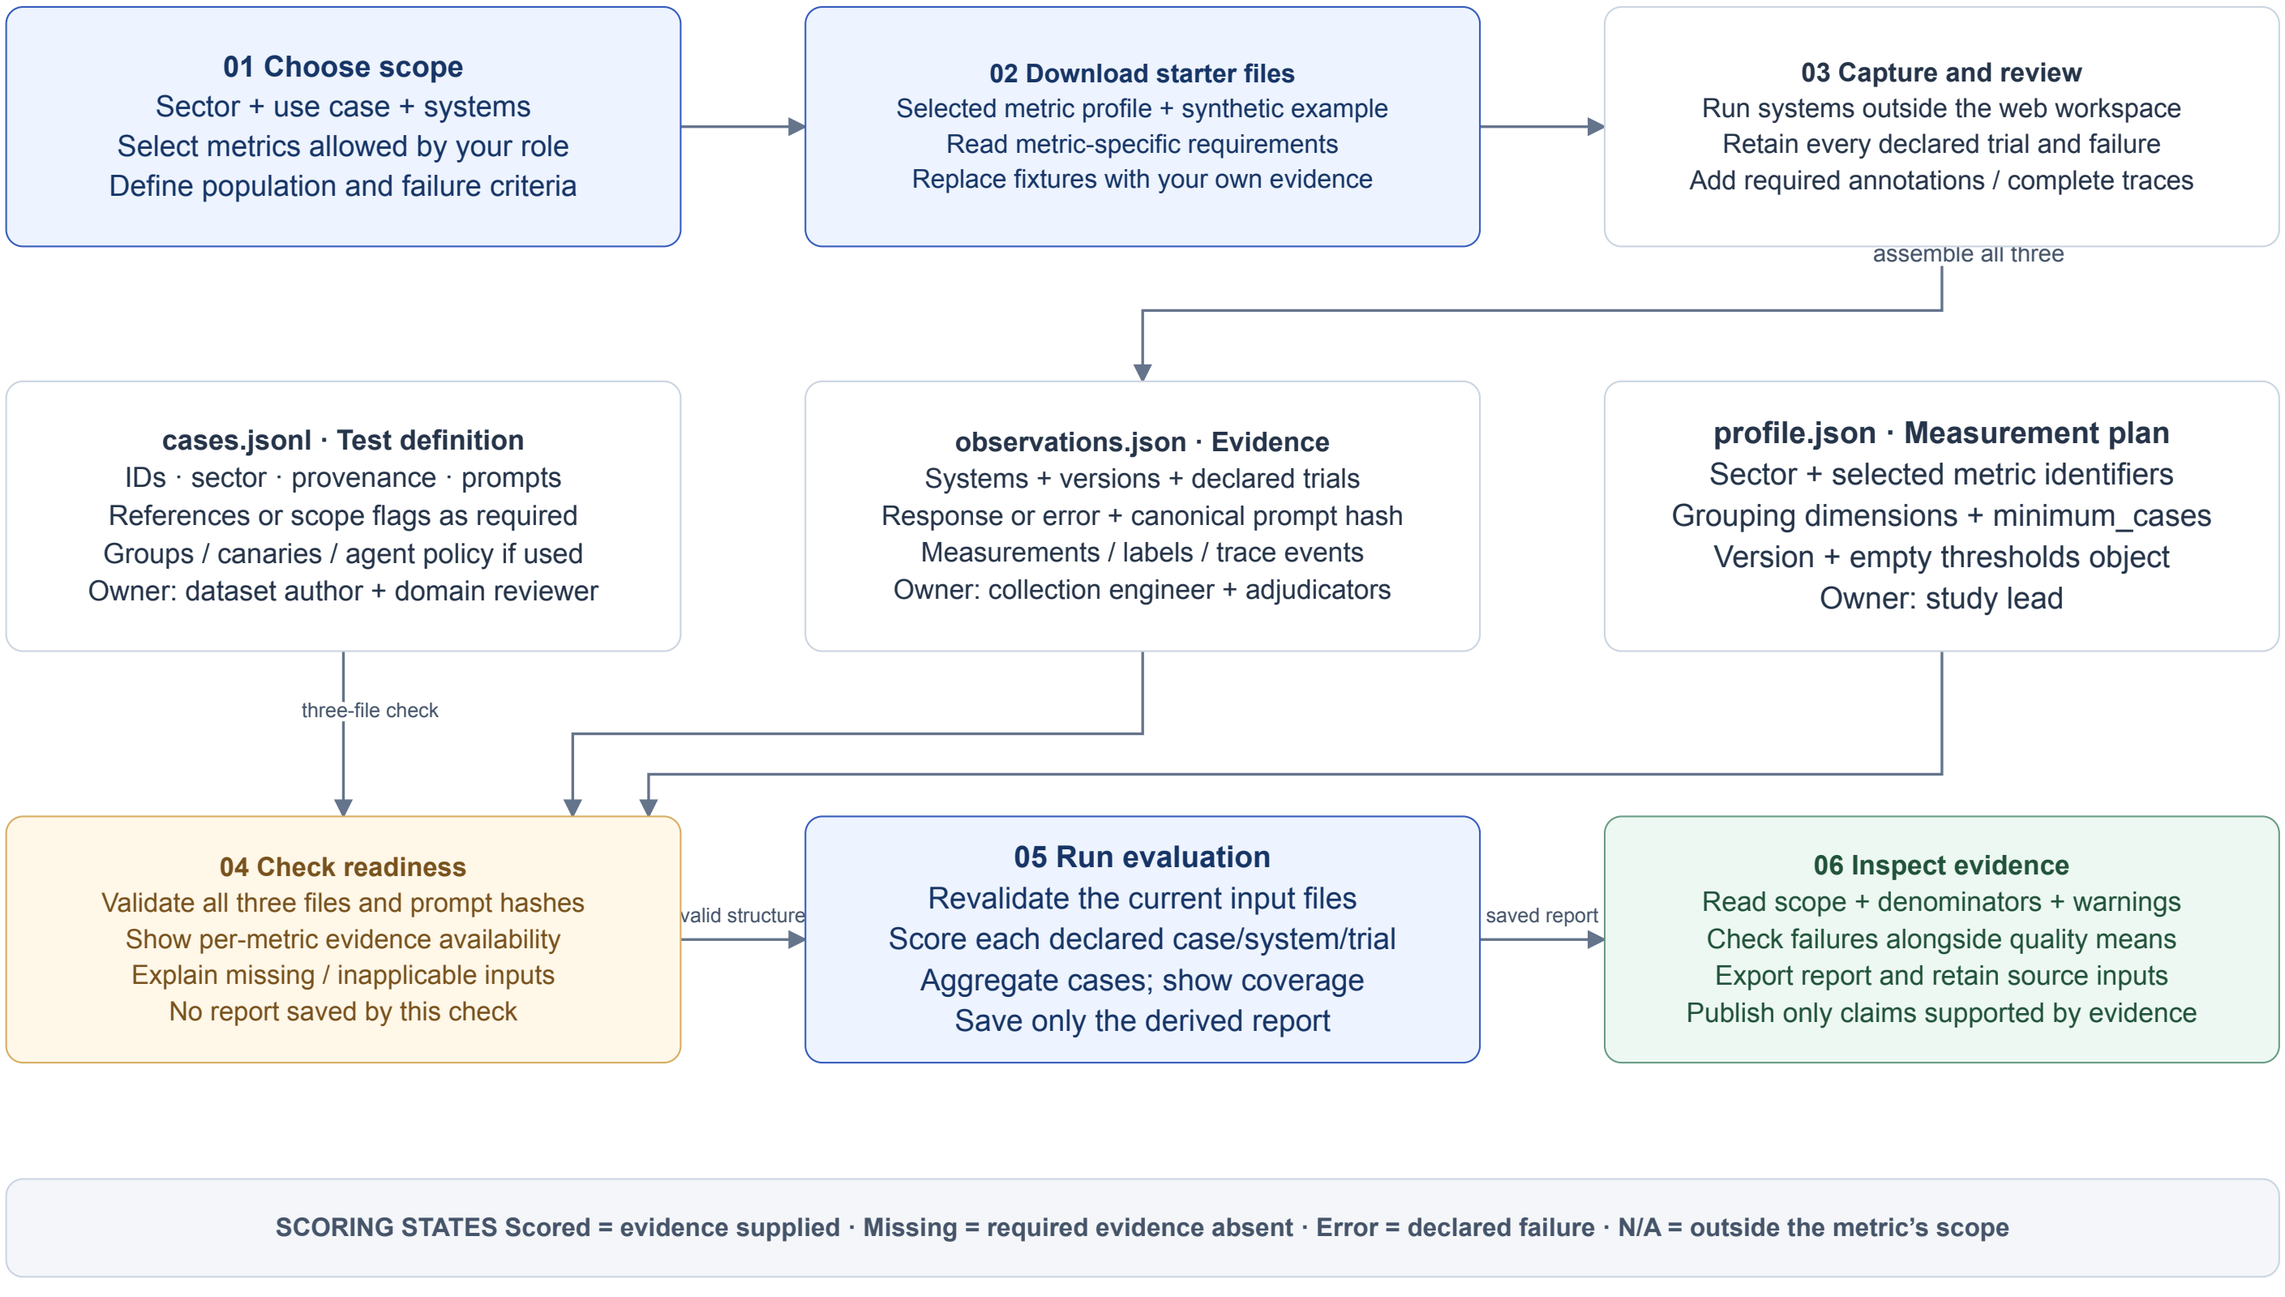

Local research workspace · external execution supplies evidence through files

DEPLOYMENT BOUNDARY One device · loopback HTTP · local files and database · no public hosting, cloud sync or provider API calls

02 · Data provision and readiness

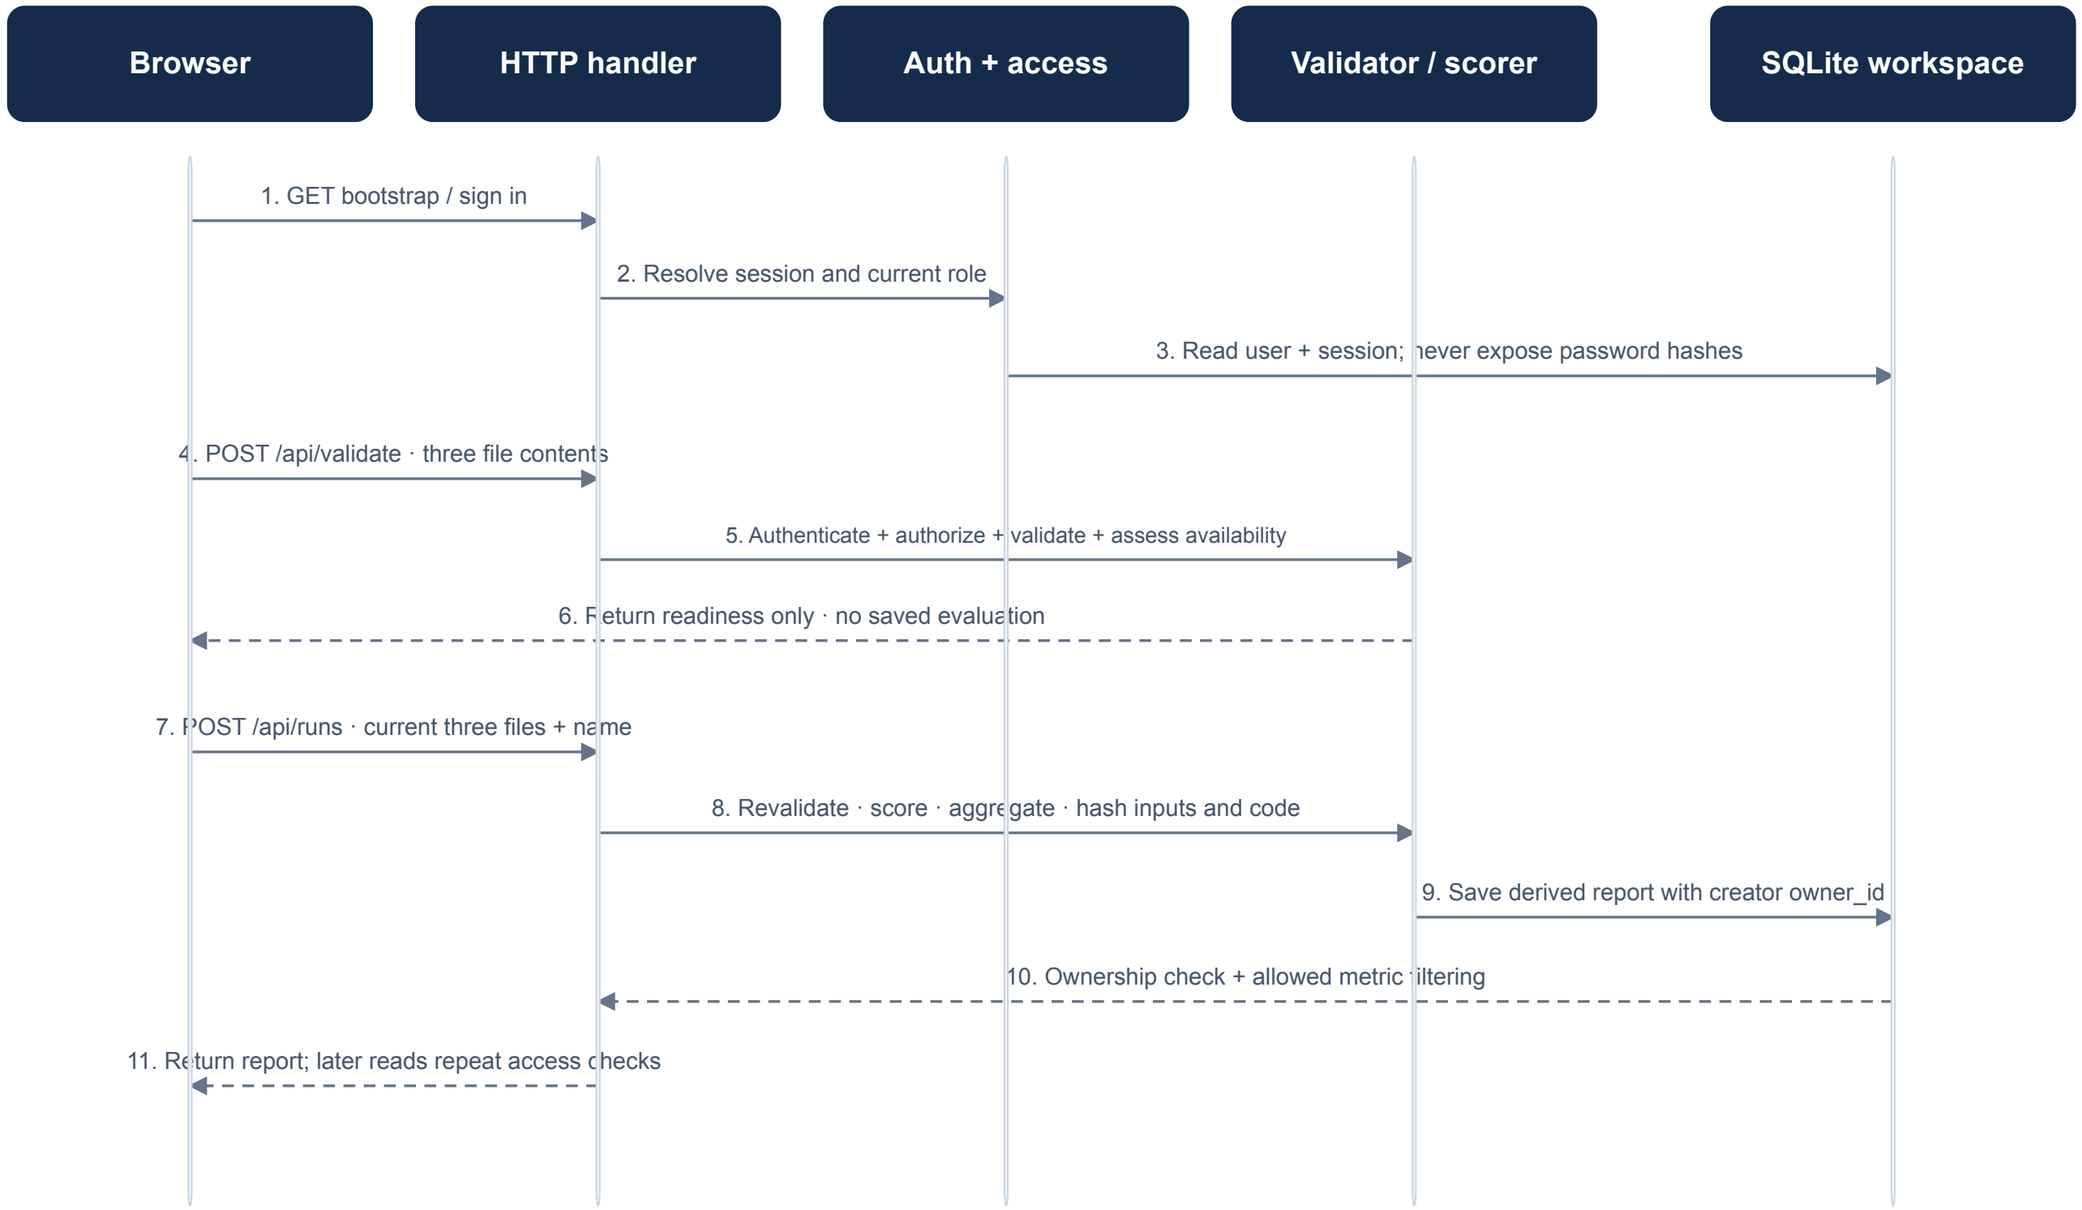

Prepare only the evidence your selected metrics need; validation is not scientific validation

SCORING STATES Scored = evidence supplied · Missing = required evidence absent · Error = declared failure · N/A = outside the metric's scope

03 · Request and evaluation sequence

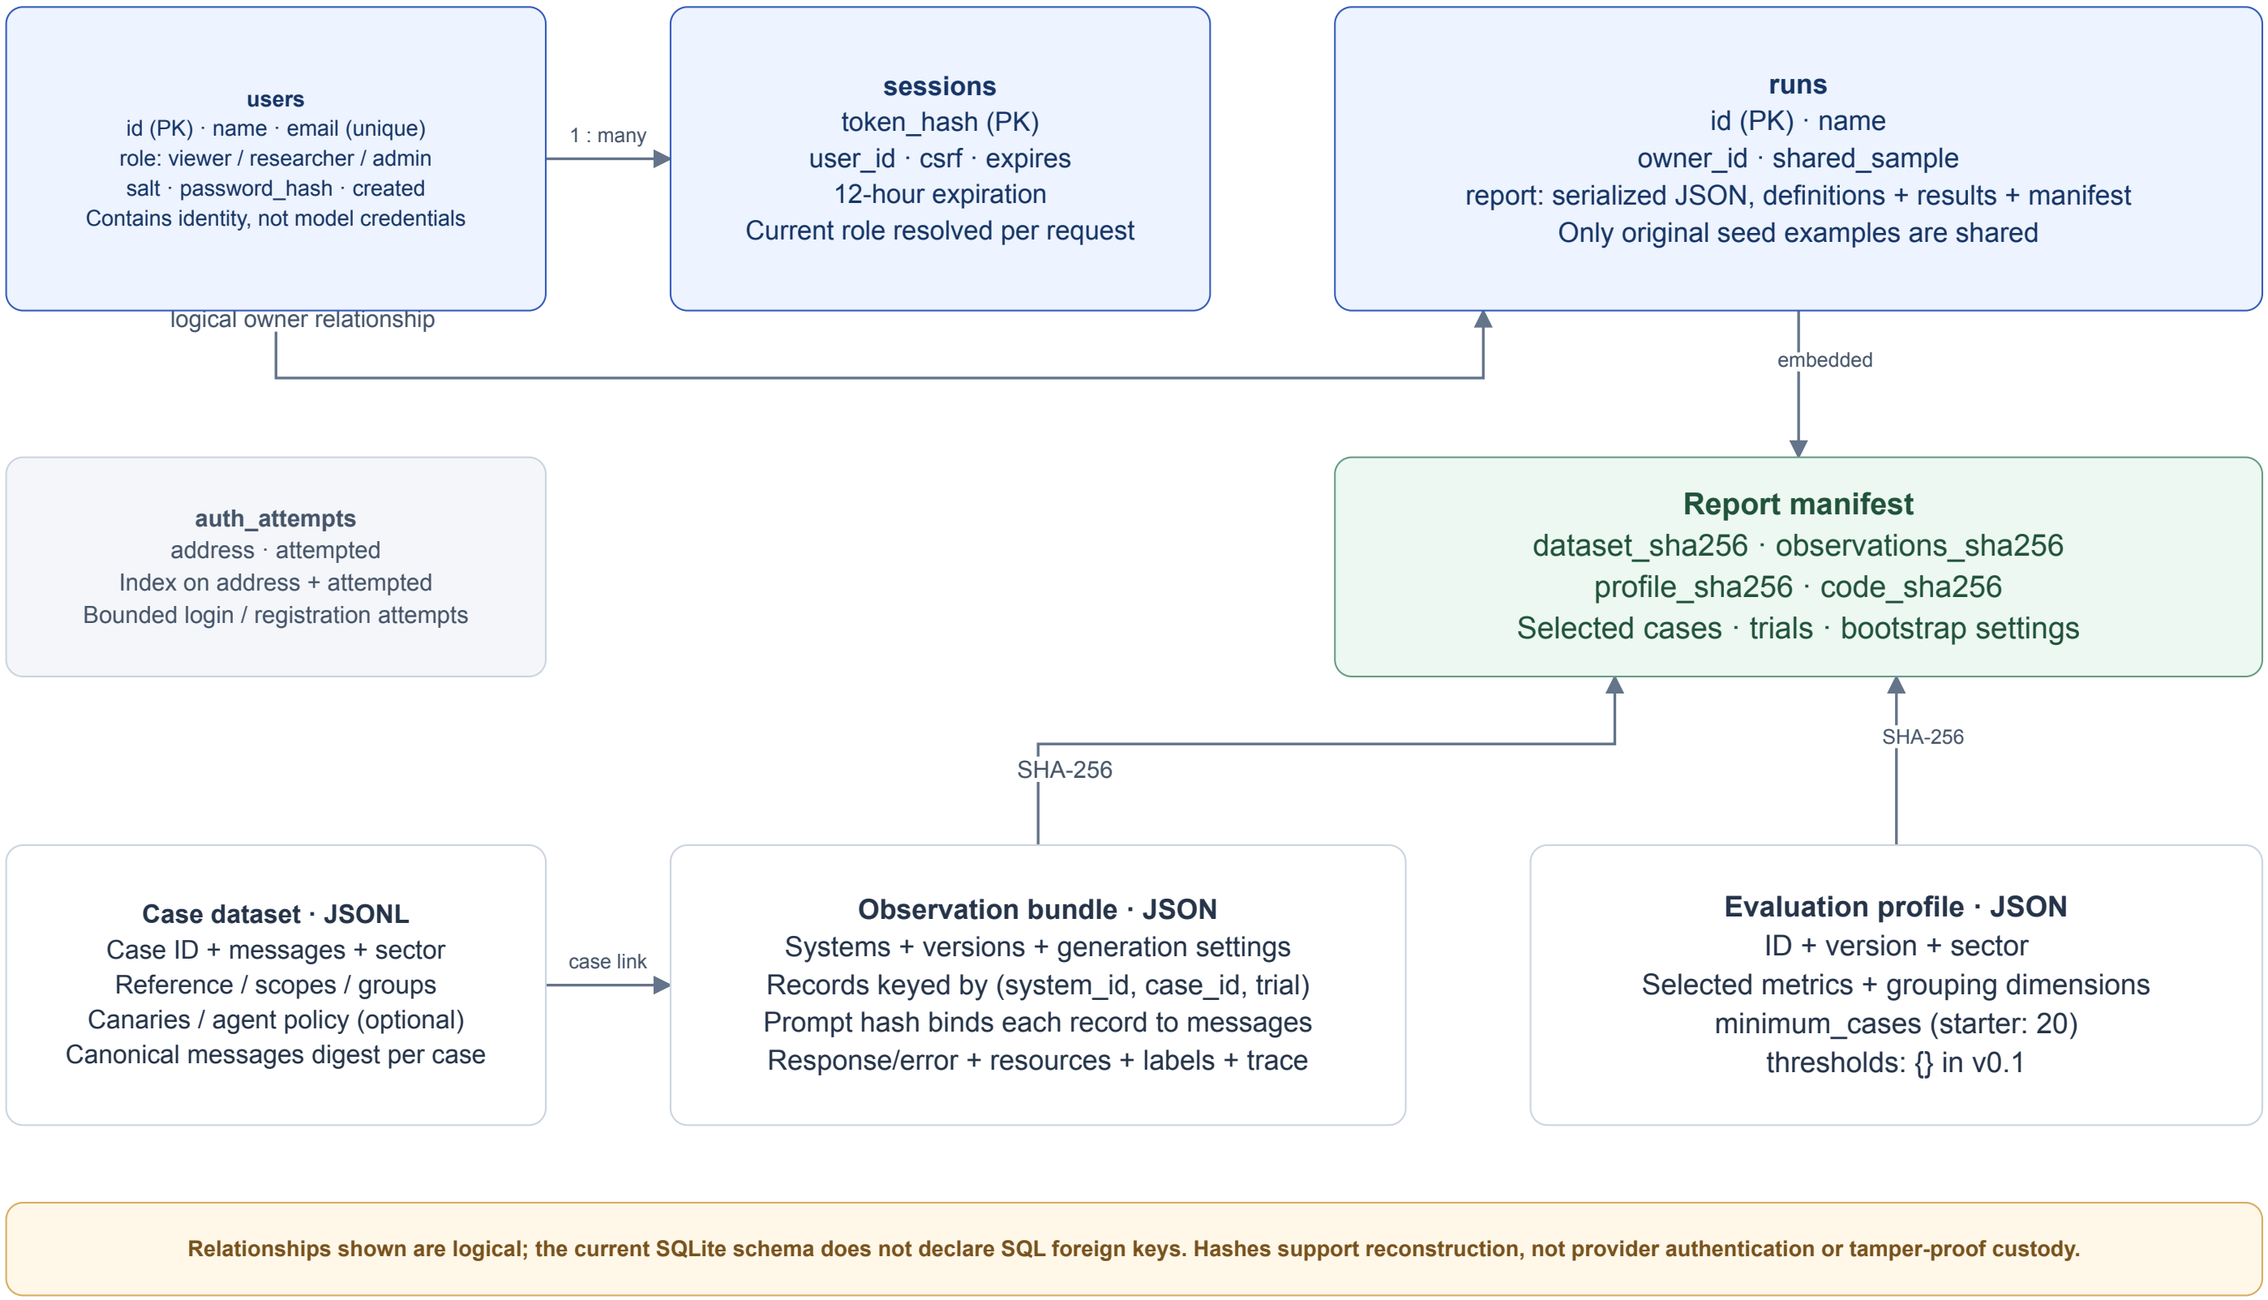

Authorization applies to direct API requests; the evaluation endpoint never trusts an earlier preflight

INVALID RUN → 400; INVALID PREFLIGHT → 200 + valid:false · NO SESSION → 401 · NO PERMISSION → 403 · INACCESSIBLE REPORT → 404 · BUSY EVALUATOR → 409

04 · Logical data and evidence model

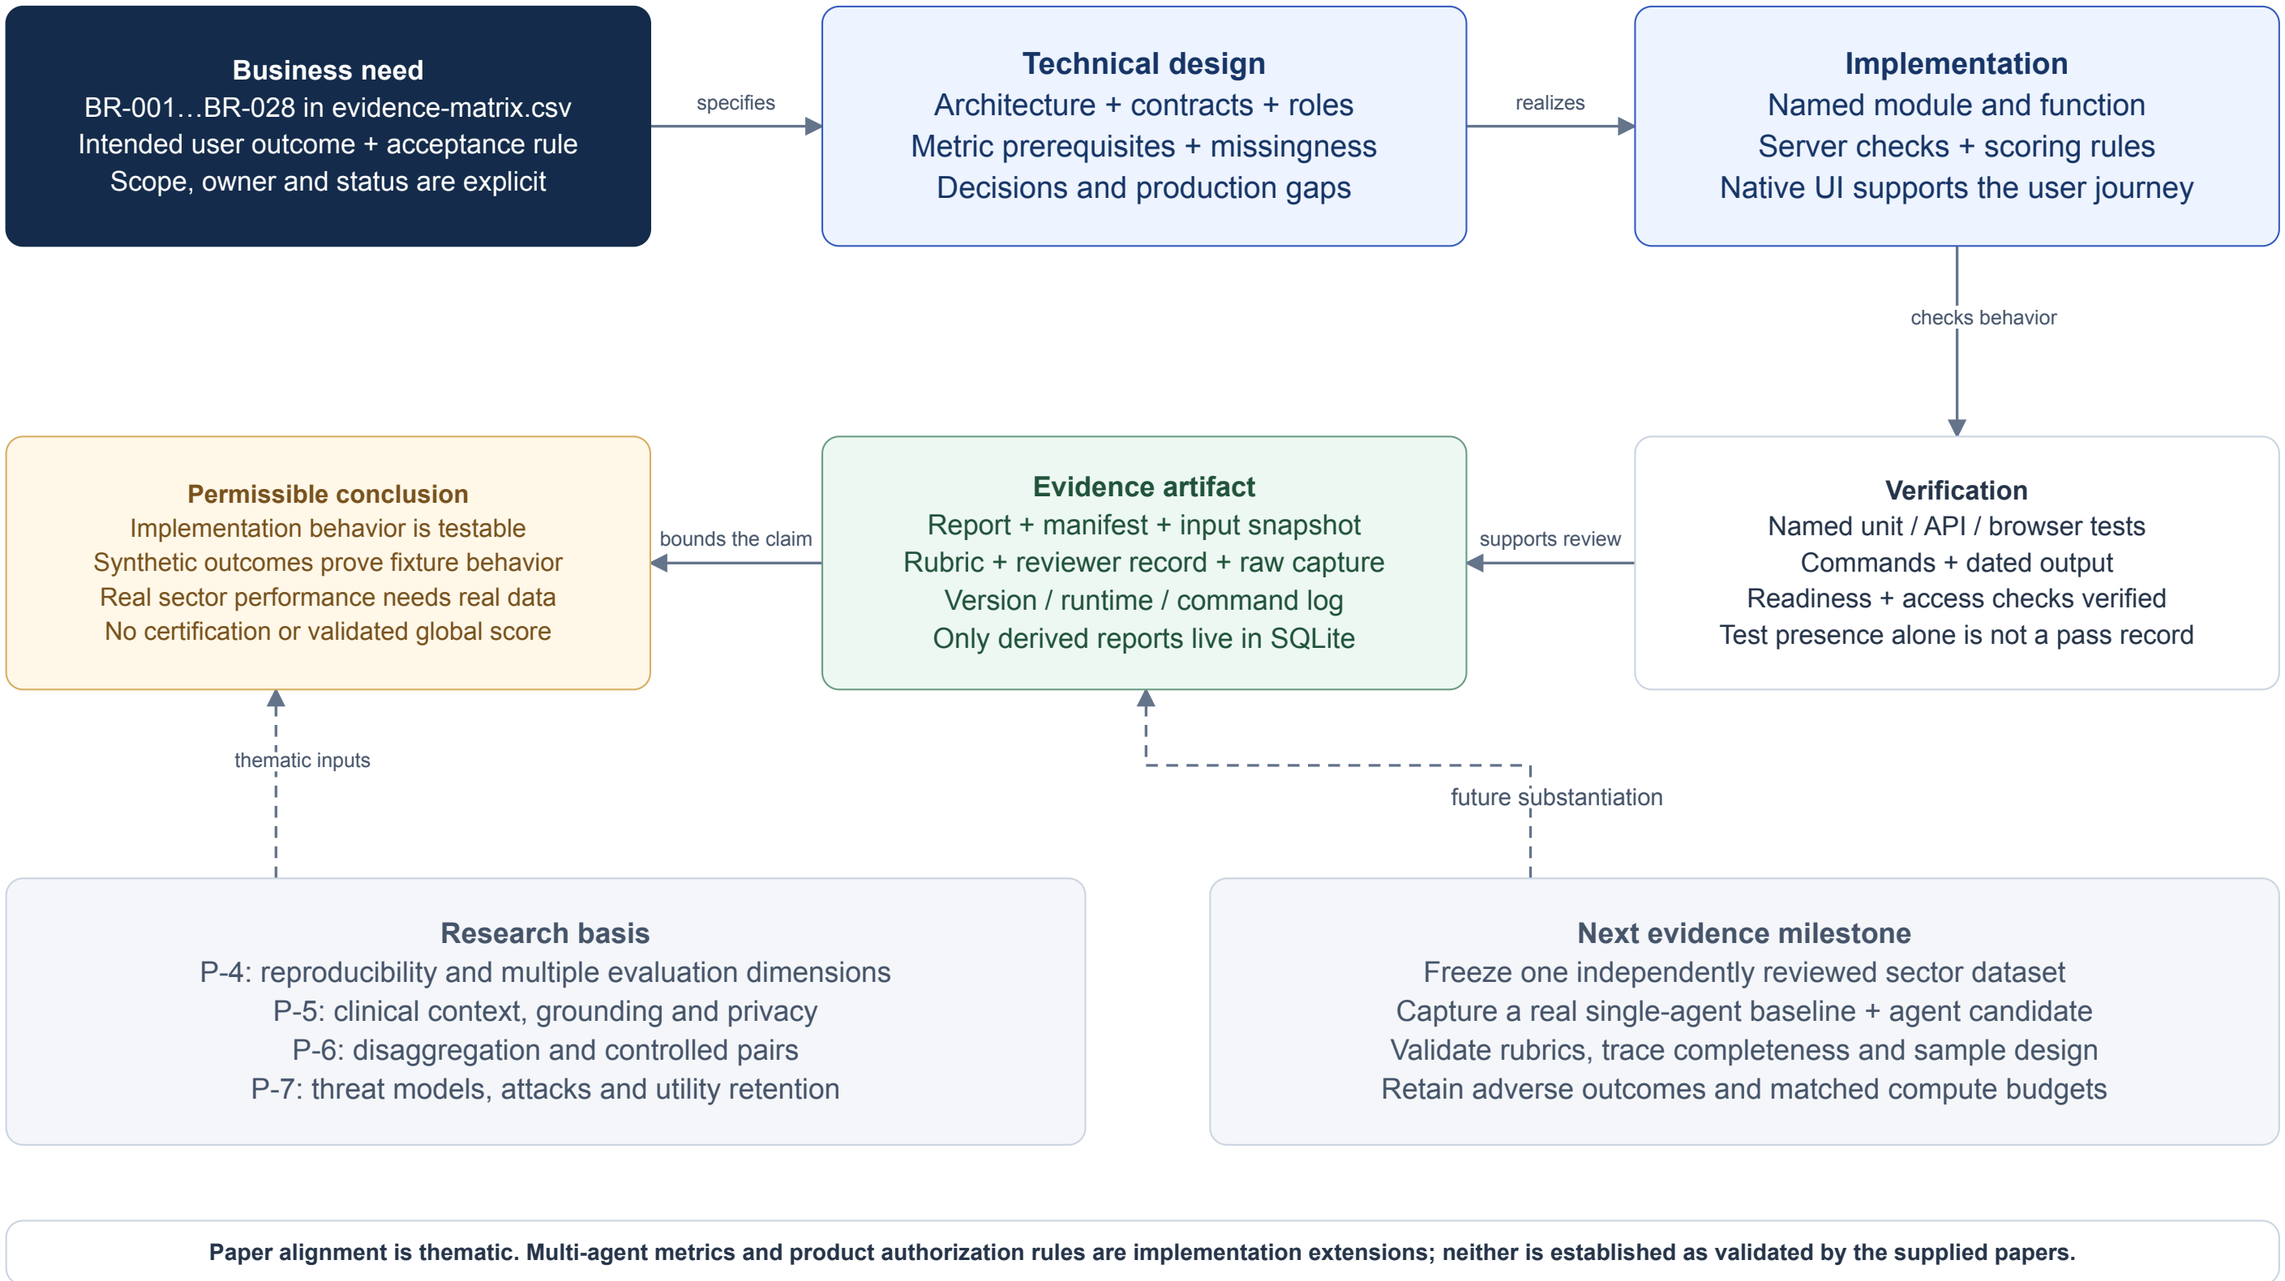

SQLite stores identity and derived reports; source input files are retained separately by the research team

Relationships shown are logical; the current SQLite schema does not declare SQL foreign keys. Hashes support reconstruction, not provider authentication or tamper-proof custody.

05 · Requirement-to-evidence chain

A traceable claim links a business need to executable behavior, a check, and preserved evidence

Paper alignment is thematic. Multi-agent metrics and product authorization rules are implementation extensions; neither is established as validated by the supplied papers.
